ABSTRACT

This thesis concerns the analysis, design, and partial implementation of a software package to automate the present manual system of conventional ammunition management onboard most ships of the U.S. Navy. Structured analysis and design techniques are utilized in the development and approximately one quarter of the application programs have been implemented.

The system is designed for stand alone operation on an IBM compatible microcomputer using the relational database package dBase III Plus by Ashton-Tate.

Follow-on work would consist of completing the application programs, select a pilot vessel and install the system, collect user comments, and modify the system as necessary.

I. INTRODUCTION

A continuous chain of ammunition, fuel and equipment is the life blood of a military organization in wartime. The incredible speed and attrition of modern warfare requires the proper placement, both in type and quantity, of ammunition in peacetime to meet the expected demands of a major conflict.

The world-wide commitments of the United States and its allies dictate a logistics system which is exceedingly complex. The global stockpiling of conventional ammunition is perhaps one of the more complex problems military planners must solve. Not only does this stock require very accurate accounting and physical security, but it is perishable in nature and its serviceability must be continually reviewed. During the Vietnam war, Navy ammunition procurement reached a high of \$988 million [Ref. 1: p. 24] with world-wide inventories valued at approximately \$7 billion dollars. It was during this period that the Chief of Naval Operations directed the establishment of a single point of reference within the Navy for conventional ammunition management. The Chief of Naval Material was given the responsibility for the establishment of a Conventional Ammunition Integrated Management System (CAIMS). One of the prime operational purposes of CAIMS [Ref. 2], was to improve the quality of ammunition stock status reaching higher echelon logistics planners. CAIMS is the point of reference regardless of inventory management or ownership responsibilities. Perhaps most important to the end-user, it was the stated policy of CAIMS to minimize the reporting burden of field activities. For example, ships were to report expenditure and inventory information to CAIMS only, and CAIMS would further distribute the information as necessary to other interested parties.

CAIMS was established and is directed by the Navy Ship's Parts Control Center (SPCC) at Mechanicsburg, PA. Program guidance is promulgated by SPCC [Ref. 3] and is further defined with specific implementing and reporting instructions in Fleet Commander instructions [Refs. 4,5].

The program has been successful in many respects, however several audits in the early 1980's conducted by the US General Accounting Office (GAO) and the Naval Audit Service found significant discrepancies between on-site local records and CAIMS data. This brought into question the Navy's ability to maintain accountability for it's

\$7 billion plus ammunition inventory [Refs. 6,7,8]. Future negotiations for ammunition appropriations depend on the mutual assurance of a credible inventory management system. The timely and accurate reporting from the hundreds of field activities and ships is critical therefore to the success of the overall system.

Although CAIMS as a whole has become highly automated, linking SPCC, the major stock points, and other organizations in the logistics hierarchy, the majority of end-users enjoy no such capabilities.

A. PURPOSE

This thesis will suggest a method to automate the present manual record keeping, report writing, and inventory control procedures in use on nearly all US Navy surface and submerged combatants. It is felt that the present procedures contribute to the high error rate in transaction reporting and inventory management. For activities that can dedicate an individual or individuals to the sole task of properly keeping the necessary records and generating the required reports, automation may seem unnecessary. However, the proposed system will increase the accessibility of ammunition and inventory information, greatly reduce storage requirements, and reduce the time required to manage the system. Therefore any activity should benefit and avail itself of a properly designed system that satisfies the functional requirements. The fact is, most ships do not have the luxury of assigning an individual to study this system and become an expert. The list of important administrative and record keeping tasks on a typical naval vessel often exceeds the crew size by a large margin. This thesis then will also attempt to lessen the administrative burden on weapons department, and in some cases supply department, personnel who are charged with the responsibility of conventional ammunition management.

This automated software solution shall be called the Shipboard Ammunition Management System (SAMS) and shall encompass all areas of routine ammunition management. The scope of this thesis will carry the project through the analysis, design, and partial implementation of critical areas of the application programs. Complete implementation and additional research shall be discussed in Chapters 5 and 6. It was particularly desired to start the implementation in this thesis because many good ideas never seem to bridge the void between paper and code on a project as restricted in time as a thesis necessarily is.

B. MOTIVATION

The impetus for this project came from the observation of the need by this author during several tours of duty on submarines of the Atlantic and Pacific Fleets. Although the quantities of conventional ammunition carried onboard submarines is considerably less, in quantity and variety, than most surface combatants, it was still obvious that an automated system could greatly improve the efficiency of the system. As discussed earlier, the many necessary administrative functions onboard a vessel generally do not decrease in proportion to crew size, so many smaller vessels suffer more in this respect. Additionally, enlisted rate training is particularly brief in the areas of conventional ammunition management [Ref. 9: p. 12-1]. Officer training is essentially nil in this area also. Therefore, the accurate and timely reports that CAIMS requires to maintain an accounting of Navy assets is being furnished by people with little time or training to become proficient in yet another administrative task. Now obviously, shipboard personnel are using the available publications and are supplying reasonably accurate information to the CAIMS system otherwise there would be much higher level attention to this problem. This author contends that SAMS will make more time available for important operational and weapons employment training.

Automating a previously manual task requires consideration of the operator's ability to operate the system by back up methods when necessary. The automated system must not be so abstract and "automatic" that the manual skills and knowledge of the underlying procedures are forgotten. Therefore, any system of this type must be instructive as well as functional. Such a system has elements of an expert system. It is developed by previous users who have acquired the proper education and training to implement a software solution, and pass on that expertise to the current users while satisfying the functional requirements. This type of user interface could become extremely tedious if the system is used frequently and so a balance must be struck between efficiency of data entry and the degree of explanatory information.

Lastly, it is unfortunate that the very personnel who require relief from administrative burdens often have neither the time or training to affect the change to automation. Thus it is particularly appropriate that shore commands and the Naval Postgraduate School solve these types of problems in addition to more basic research. The making available of time to train in relevant warfare topics is at the heart of current drives to reduce administrative and paperwork tasks within the Navy.

C. CHAPTER OUTLINE

Chapter 1 has discussed the importance of accountability and inventory management of conventional ammunition within the Navy. A broad discussion of the logistics hierarchy has highlighted the necessity of accurate and timely information flowing up from the hundreds of field activities and ships. The purpose of this thesis was stated to be a software application package to automate the tedious and complex manual record keeping required at the fleet end-user level.

Chapter 2 will describe the present manual system of ammunition management in detail and point out the problems inherent in these procedures. The references for the manual system will be examined to illustrate the difficult task of interpreting this large volume of often overlapping documentation. Examples of data redundancy will be examined to help understand why internal record keeping is more complex than it should be. Finally, the lack of standardized procedures for the end-user management of ammunition will be discussed in light of the improvements available from a standardized software application.

Chapter 3 describes the methodology for the development of a software solution to the problem. The analysis phase is considered in detail and system data elements are identified. A tailored Data Element Dictionary (DED) is developed and Data Flow Diagrams (DFDs) illustrate the proposed system as levels of process descriptions. Finally, the advantages of a database solution and normalization theory are discussed.

Chapter 4 provides the technical details of the relations, fields, indexes and keys with respect to relational database design and normalization. The transition from logical to physical process descriptions takes place with the development of structure charts for the system. The qualities of good modular design are discussed and the effects programming in dBase III Plus has on these qualities.

Chapter 5 discusses the application code that has been implemented for this thesis and the reasons for selecting these programs. Coding design decisions and style are discussed in light of the potential end-users and frequency of use. System expandability and flexibility are highlighted.

Chapter 6 contains recommendations for future research and comments and conclusions.

The Appendices will consist of:

- a. Data Flow Diagrams
- b. Data Element Dictionary
- c. Program Directory

- d. Structure Charts
- e. Program Code Listings
- f. Programs Diskette

II. PRESENT MANUAL AMMUNITION MANAGEMENT / PROBLEMS

Naval units are required to maintain records and submit reports which provide accountability of conventional ammunition and allow reconciliation of Navy ammunition assets world-wide.

As a preface to a discussion of the inventory control procedures, it is worthwhile to review the item control methods used within the Navy. The military services participate in the Federal Cataloging System [Ref. 10: sec. 2032]. Most NATO countries also participate in the United States Item Identification Code, for military standardization purposes, under NATO Standardization Agreement 3151 [Ref. 10: sec. 2035]. All conventional ammunition items at the end-user level should conform to the Federal Cataloging System. These items are assigned a National Stock Number (NSN) by the Defense Logistics Services Center (DLSC) at Battle Creek, Michigan.

An NSN is a 13-digit stock number, see Figure 2.1 , and is composed of a 4-digit Federal Supply Classification (FSC) followed by a 9- digit National Item Identification Number (NIIN). An FSC describes a "family" of items of supply sharing such common characteristics as nomenclature, end application, or physical construction. For example, the FSC 1345 is the bomb "family" of conventional ammunition.

Figure 2.1 National Stock Number breakdown.

The first two digits of the NIIN are the National Codification Bureau (NCB) code, and are essentially a country code (and in some publications referred to as that), within the NATO framework. The United States is assigned the NCB "00" and since it is always part of the NIIN we will no longer distinguish it from the NIIN. A NIIN uniquely identifies an item in the Federal Cataloging System.

Item identification unfortunately gets a bit more complicated. The Department of Defense (DoD) has established a Department of Defense Ammunition Code (DODAC), which is an 8-digit code consisting of a 4-digit FSC (same as previously mentioned), and a 4-digit DoD Identification Code (DODIC). See Figure 2.2 .

Figure 2.2 Department of Defense Ammunition Code.

To proceed further, the Navy Ship's Parts Control Center (SPCC) has assigned a 4-digit Navy Ammunition Logistics Code (NALC) to certain end round missiles and torpedoes. The NALC is similar to the DODIC except that it is assigned by SPCC rather than DLSC. See [Ref. 11]. NALC's are listed in the Stock List of Navy Ammunition, TWO10-AA-ORD-010 [Ref. 12], along with the DODIC if a NALC has not been assigned.

A particular item will have a unique FSC, a unique NIIN, but may have either a NALC or a DODIC. Figure 2.3 may help illustrate this point.

Figure 2.3 Identification Number Composition.

Until recently, Navy ammunition items were tracked by NALC vice NIIN, and it is obvious that since a NALC does not uniquely describe an item but a group of very similar items, accurate stock knowledge was not possible for the end-user accounts.

Items of the same NALC/DODIC are normally functionally compatible, but may have small differences. For example, NALC A015 is for 12 gauge shotgun shells, 00 buck, but one NIIN is for a shell with paper cases and one has plastic cases. Apparently recognizing the lack of accuracy that results from NALC reporting, SPCC is now emphasizing NIIN reporting on all documents. An automated system should enforce this more logical approach, while still maintaining the NALC identity because it is still widely used for referring to an ammunition type. The Stock List of Navy Ammunition, mentioned earlier, contains cross referencing for this purpose, as well as being the prime source of generic information about conventional ammunition within the Navy, Coast Guard, and Marine Corps. It is updated regularly on microfiche and held by all activities with Navy ammunition.

To conclude this discussion of item identification, two additional terms are important. Ammunition Lot Numbers (ALN's) or just Lot Numbers, are assigned by loading, manufacturing, or assembly activities to identify homogeneous material that should function in a "near identical" manner. The lot number is also important to allow tracking, to maintain performance and surveillance records, and allow suspension or recall if necessary. New items are assigned ALN's in accordance with MILSTD-1168A, however much older ammunition is still in the inventory with less uniform lot number formats. Finally, serial numbers are assigned to high value or special interest items to allow individualized tracking.

A. INVENTORY RECORDS

Three types of record cards are used onboard ships for inventory control.

1. Master Stock Record Card

The Ammunition Master Stock Record Card, NAVSUP Form 1296, Figure 2.4 , is kept for each NALC/DODIC carried onboard. The card provides a history of the transactions that have occurred effecting the quantity or status of that item. Changes to the quantities in the inventory can take place by receipts, issues, or expenditures. Expenditures can occur due to combat operations, training, test and evaluation, exercises, and other reasons. Each form of transaction has a one character code, the Transaction Code, that describes it. These codes are explained and listed in the SPCC CAIMS manual [Ref. 3: p. 8-5-35].

If material is received or issued it will have a corresponding document number, which is composed of the activity's Unit Identification Code (UIC), the 4-digit julian

date, and a 4-digit serial number. The serial numbers are assigned sequentially and the recommended range is 8000 to 8999. They may then repeat, however used in conjunction with the julian date, a requisition can be uniquely identified. See Figure 2.5

Figure 2.5 Document Number.

Reclassification of onboard inventory items may occur when SPCC, or the Inventory Manager or Technical Manager, determines that a particular lot of ammunition should be suspended, used in a limited fashion, or considered unserviceable. Fleet users are notified of such changes by Notices of Ammunition Reclassification (NAR) messages. Approximately annually, all effective NAR's are incorporated into NAVSEA Publication TWO24-AA-ORD-010, Ammunition - Unserviceable, Suspended, and Limited Use [Ref. 13]. A particular item's degree of serviceability is described by its one character Condition Code, all of which are fully discussed in Appendix C to Reference 13 .

On the Master Stock Record Card, the on-hand balances are subdivided among the various condition codes that the activity holds for a particular NALC. Condition Code Alpha, unrestricted, is naturally the most common.

The Naval Sea Systems Command (NAVSEA) publishes allowance lists for each vessel which depend on its type and configuration. The lists contain ammunition type and quantity authorized, as well as the quantity of certain NALCs that may be used for training. The master record card is used to record these numbers and the computed unexpended training allowance remaining for the fiscal year.

Any changes in quantities or condition codes require that an Ammunition Transaction Report (ATR) be submitted. This report will be more fully described later.

but the Master Stock Record Card is used to associate the ATR number with the particular transaction line item on the card.

Finally, various other codes are recorded on the card which are obtained from one of several references:

1. Packaging Remarks: References 12 or 14
2. Logistics Code-NALC: References 12 or 14
3. COG-Cognizance Symbol: Reference 12
4. MCC-Material Control Code: Reference 12
5. DOT-Department of Transportation Hazardous Material Code: Reference 14
6. NHEEW-Net Explosive Weight: References 12 or 14
7. C.G. Haz. Cl.-Coast Guard Hazardous Material Class : Reference 14

2. Lot/Location Card

The Ammunition Lot Location Card, NAVSUP Form 1297, Figure 2.6 , is completed for each lot number within a NIIN. There are only a few new concepts on this card that have not been previously explained, so the explanation will be brief. The consignor consignee is the shore activity or operating unit to which the issue was made or from which the item component was received. This card contains much information previously entered on the Master Stock Record Card.

3. Serial/Location Card

The Ammunition Serial/Location Card, NAVSUP Form 1356, Figure 2.7 , is completed for items that require SLIT tracking. Serial/Lot Item Tracking (SLIT) is a system whereby certain ammunition items are designated for increased tracking and surveillance. These items may require identification by lot number, serial number, or both when reporting transactions. This distinction is indicated by the Material Control Code (MCC):

<i>MCC</i>	<i>Reports</i>
B	Lot Number
C	Item Serial Number
E	Lot and Item Serial Number

Items that do not require SLIT reporting will not have an MCC assigned. MCC Bravo ammunition is adequately documented on the Lot/Location Card. Items with MCC Charlie and Echo require individualized tracking with the Ammunition Serial/Location Card.

The only new item here is the Maintenance Due Date (MDD), which is the month and year of the component's next scheduled maintenance. MDD's are assigned to MCC Charlie and Echo items only. Figure 2.8 may help to illustrate the relationships between the various stock cards.

4. Discussion of Inventory Record

As Figure 2.8 demonstrates, normally 2 and occasionally 3 of the stock record card types are required to describe an ammunition item. With no other device available, the Master Stock Record Card must hold all the transaction information for every transaction (i.e., document number, type, quantity, etc.). It must hold all of the allowance information, or you would have to reference the Allowance List each time you needed that information. It holds much generic data about the item which does not change regardless of transactions or quantity in the inventory. The alternative however would be to look up information, each time you were interested, in at least four very voluminous publications.

The Lot Location card subdivides each NIIN by lots, and much information is repeated. The only new data items are the lot numbers. The Serial/Location cards likewise duplicate data.

It is quite obvious that maintaining all the required records for even a small ship's inventory, say at least 40 NALCs, would be extremely tedious. A large vessel with perhaps hundreds would demand full time attention. It is this author's experience that much of the repetitive information would not get entered properly, and the initial construction of a set of cards would be an onerous task. Multiplying those man-hours for all the ships involved results in considerable non-operational training time.

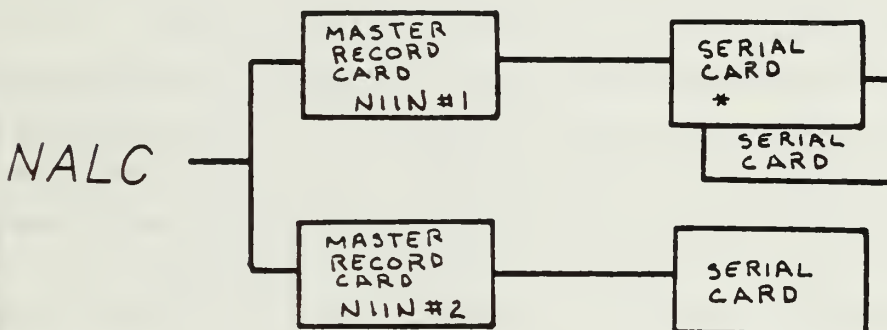

Ideally the inventory records should contain information that deals only with that particular batch of ammunition, namely:

1. NIIN - what is it?
2. Condition Code - what can it be used for?
3. Activity Classification Code - who is it for?
4. Quantity - how many are there?
5. Storage Location - where is it?
6. MDD - when does it need maintenance?
7. Lot Number - what lot is it?
8. Serial Number - which one is it?

Non-SLIT and Lot Controlled Items (MCC "B")

Serial Number Controlled Items (MCC "C")

* Each card can record about 40 serialized items.

Serial and Lot Controlled Items (MCC "E")

Figure 2.8 Ammunition Stock Card Relationships.

This information can *not* be looked up in a publication because it deals with the particular articles at hand. Other information listed on the stock cards is of general nature and can be looked up, indicating that we could locate it in one central place and reference it when needed. Therefore we would not have to repeat it on every card. This is one of the important concepts of automation that can be used in many ways as chapter 3 will demonstrate.

B. REQUISITION, TURN-IN/TRANSFER, RECEIPT

1. Background

Naval vessels are required to maintain 100% of their authorized allowance on board or on order, so as to be ready for immediate combat operations. Certain exceptions apply which are spelled out in the SPCC CAIMS manual [Ref. 3: p. 8-2-2], and may be modified by fleet commander instructions [Ref. 4,5]. Reasonableness dictates how small an order should be placed to satisfy these requirements, of course, where ammunition is concerned, too much is better than not enough!

A few more definitions are appropriate at this point. Activity Classification Codes (ACC) describe basically who the ammunition is for. It may be carried by a ship to satisfy its own offensive and defensive armament needs, in which case it is ACC Alpha ammunition. However, other ammunition could be carried for embarked Marines, aviation units, or for underway replenishment of other ships. Each of these other recipients causes the ACC to be different. Most medium to small ships and submarines only carry ammunition for their own use, but most large ships have ammunition on board for other purposes and thus they must account for it separately (ie- a separate deck of inventory cards). This makes the ACC an essential data element for each ammunition record. Chapter 8 of the CAIMS manual [Ref. 3: p. 8-5-34], lists and describes all of the ACC codes.

Associated with the concept of ACC, are the three types of allowance lists a ship may have. A Shipfill Allowance List authorizes the quantities and types of ammunition for own ship's use. A Mission Load Allowance List is that ammunition carried to support associated ships or aircraft squadrons; usually aircraft carriers and tender type ships. A Cargo Load Allowance List is normally held by designated cargo or logistic type ships (AE, AOE, AOR, etc.) for replenishment of other vessels.

All naval vessels, as well as the other services and many government agencies, submit requisitions and transaction reports in Military Standard Requisitioning and Issue Procedures (MILSTRIP) format [Ref. 3: Chapter 8]. This system serves to

standardize procedures for efficiency and economy. It allows machine readable logistics traffic by specifying data elements, codes, and formats. Until recently, transaction reporting was done in normal narrative message format which had to be transcribed to MILSTRIP format at a shore activity with ADP capability. New instructions from SPCC [Ref. 3], and those still in production at fleet headquarters, now direct a format that is machine readable, reducing the chance of error in transcription or key punching. SPCC is linked, via ADP equipment and telecommunications with all major stock points, many minor stock points, and other logistics organizations. Ships submit manual requisitions or send messages which are entered into the CAIMS at a shore activity.

The Defense Automatic Addressing System (DAAS), with primary location in Dayton, Ohio, is a telecommunications system which was designed to effectively route logistics traffic from all the services. DAAS computers can receive messages, perform some format error checking, determine the addresses, and route them over the quickest path to their destination. DAAS functions over the Automatic Digital Network (AUTODIN). The message format that is acceptable to DAAS is slightly different, and the requirements for use more restrictive, than a normal naval message. However when applicable, it is the most efficient way to route logistics traffic. The SAMS system should allow for transmission in either format as well as manual requisitioning.

2. Requisitioning

Ships and other naval units may submit requisitions for conventional ammunition in one of three formats as previously alluded to. A manual requisition, DD Form 1348, Figure 2.9 , may be completed and physically delivered or mailed to a shore weapons facility. The shore activity enters the requisition into the CAIMS with their ADP equipment, SPCC routes the requisition to the appropriate Inventory Manager (SPCC,NAVAIR,NAVSEA,NMWEA,JCMPO), and an appropriate stock point is selected to deliver the material.

A message requisition may be prepared in DAAS format, Figure 2.10 , and electrically transmitted. A requisition line item on a DAAS message is printed on one horizontal line or 66 characters, with no separations. A DAAS message may also contain followup actions, modifications, cancellations and other logistics actions besides requisitions. The type of action is determined by the document identifier, column 1-3. The Routing Identifier (R I), column 4-6, is analyzed and the line item sent to its addressee. In this format the requisition is fully machine readable.

EDITION OF 1 AUG 61 MAY BE USED UNTIL EXHAUSTED

Figure 2.10 DAAS Message Requisition Format.

DAAS has restrictions however. There can be no narrative remarks, the classification must be UNCLASSIFIED, and the R/I must be a continental United States (CONUS) activity connected to AUTODIN. Usage of DAAS by afloat units is somewhat limited by fleet commander instructions which require narrative remarks and primary addressee other than DAAS, Dayton, OH on some ammunition items.

The last requisition format is the normal narrative naval message, Figure 2.11. It should be noted that information and codes present on any of the three formats are almost identical. Fleet commander instructions require some minor format changes. The Pacific Fleet Conventional Ordnance Management Manual [Ref. 4: p. 1-1-A-8] for example, requires that the quantity and NSN be spelled out on naval message requisitions to prevent confusion in the event of a garbled message. In any case, this format is not machine readable and must be entered into CAIMS at a shore activity. It is more flexible however than a DAAS formatted message. Remarks may be included, it may be addressed to any activity, and it may contain classified information (the remarks generally are the only classified information).

The three formats are reasonably well described [Ref. 3: Chapter 8]. The codes are rather cryptic and their full names are shown below. Explanations may be found in Appendix B, the Data Dictionary.

3. Turn-in/Transfer

Ships often have to turn-in ammunition that is excess, reclassified by NARs, or requiring periodic maintenance ashore. The DD Form 1348-1 is used for this purpose, Figure 2.12. Somewhat fewer coded items are necessary on this form because the ship is physically delivering the material to another activity. Most commands also select another group of serial numbers for turn-ins, in order to differentiate them from requisitions. A separate log is maintained. The CAIMS manual [Ref. 3: p. 8-3-1], assists the user in completing the form.

4. Receipt

Ammunition is also received on DD Form 1348-1. The document number on the receipt document corresponds to the receiving ship's requisition document number, of course the possibility of being sent material that was not ordered exists. The only new data items that have not been previously discussed are the unit price and the unit of issue, both of which are listed in the Stock List of Navy Ammunition [Ref. 12].

5. Discussion

The requisition, turn-in/transfer, and receipt documents require some form of logs to be kept. A Requisition Log may contain a history of requisitions and receipts by document number (serial number). A Turn-in log would be similar. Retention of these documents provides a source of information for the future, instead of having to look up the information all over again. This is not necessarily a good practice as certain data elements may have changed in the interim. But this is just the kind of thing a busy sailor might do to save time, not recognizing the potential problems involved. Recall of the many different data items from publications can be time-consuming.

C. AMMUNITION TRANSACTION REPORTING

Transaction reporting is required for any action, event, or procedure that results in the receipt, issue, transfer, expenditure, loss, gain, reconfiguration or change in material condition of reportable material. [Ref. 3: p. 8-4-3].

The format of Ammunition Transaction Reports (ATR's) has recently been changed to allow optical scanning of the data elements which are separated by from one to four slashes, "/". ATR's have multiple formats depending on the type of transaction, the MCC of the material (i.e., SLIT or non-SLIT), and the actual type of the material. This extreme variability has traditionally caused the greatest problem, resulting in a

31

high error rate for these documents. Although the new format is more efficient in that it can be optically read and entered into the CAIMS by shore activities, it is now incomprehensible to the fleet user. Therefore each ATR must be created in a painstaking step-by-step manner, minding the format and content of each data element. ATR's are transmitted as naval messages to SPCC, with information addressees and classification depending on the type of ordnance and the type of sending platform (i.e., submarine, surface vessel). Figure 2.13 illustrates one format of ATR. The serial numbers run from 001 to 999 and then repeat, with a ship's most recent ATR indicated in the current ATR's reference line. This is to ensure that SPCC receives all ATR's from a ship without omission, and in the correct sequence. Again, multiple transactions can be listed on one message as long as the common information in the header applies to all the transaction line items. Figure 2.14 attempts to illustrate the various ATR formats, the variability is evident. Each vessel keeps an ATR log to form the primary history of the ship's ammunition transactions, from overhaul to overhaul, and to allow correction of any ATRs that were submitted with incorrect data. This log may consist of all the actual messages and a summary of each ATR with its effect on the running total of each item involved.

Properly submitted ATRs are critical for the overall functioning of CAIMS. The old adage " garbage-in, garbage-out " aptly applies, and it is sincerely hoped, by all levels, that higher echelons are not making procurement and allocation decisions based on incorrect data.

D. COMMENTS

In addition to comments made throughout this chapter concerning data redundancy, multitudes of codes, and more than a few reference publications, mention should be made of the lack of any standardized record keeping procedures. Requisitions, turn-in documents, and ATRs must be submitted, and inventory cards maintained, but no system or procedures exist for the maintenance of logs or records.

It is generally accepted that some sort of auditable system must exist to resolve discrepancies and maintain accountability. The procedures that each individual ship creates may range from excellent to poor. Some ships may have even written ship's instructions for this purpose, detailing the manual methods to be used. A software package, such as the proposed SAMS, will have several benefits besides more accurate and timely ATRs. It will keep all logs and records for the user, it will standardize procedures without requiring the user to create new logs and binders, and finally it will

all fit on a disk or diskettes. It might even save a few nervous breakdowns when new Weapons Officers report onboard to find no system in existence at all.

III. AN AUTOMATED SYSTEM DEVELOPEMENT

The purpose of Chapter II was to give the reader a basic knowledge of the records and reports presently used onboard non-automated ships of the Navy for conventional ammunition inventory control and accountability. Problems of data duplication, lack of standardized record keeping procedures, data inaccessibility, and late and inaccurate external reports as a result of these were discussed. This chapter shall develop a database management system (DBMS) solution to alleviate those problems as well as reduce the administrative burden on ship's force personnel.

A. METHODOLOGY

It is now generally accepted that systems analysis and design must follow an orderly, logical process to arrive at a system that is reliable, maintainable, efficient, and manageable (i.e. within cost and time). The Shipboard Ammunition Management System (SAMS) development has followed such a process with certain modifications that reflect the new technologies of the DBMS and its easy to use programming language.

Structured analysis and design evolved in the 1970's to bring a disciplined approach to computer system development. The 1950's and 1960's were characterized by haphazard analysis and design techniques and what Meilir Page-Jones referred to as the "Instant Karma" approach of computer system development [Ref. 15: p. 27]. Many excellent books now exist on the subject of structured techniques, [Refs. 15,16,17], so the treatment here will be brief and only as it relates to the SAMS development. Davis [Ref. 17: p. 8] defines the steps involved in a structured development, or life cycle as:

1. Problem Definition
2. Feasibility Study
3. Analysis
4. System Design
5. Detailed Design
6. Implementation
7. Maintenance

The relative weight that each step carries and the time spent in each area, of course depend on the project at hand. Most organizations use, or have used, some derivative of this basic life cycle in their system development process. A reasonable approach is to study the available structured development philosophies, modify these where advisable to accommodate new technologies and tools, and apply the best composite plan. There have been worries among structured technique advocates that the new technologies, i.e. fourth generation languages, prototyping packages, and personal computers, will compromise advances made in systems analysis and design. But, as Edward Yourdon, a prime advocate of the structured techniques, points out:

The major philosophical concepts used to build reliable, maintainable information systems, which is what the structured techniques are all about, can continue to embrace new technologies without destroying the concepts themselves. [Ref. 16: p. 6]

Chapters I and II went into some detail on the nature of the problem and defined the scope of the solution. A formal feasibility study was not conducted, however the major points of such a study were considered [Ref. 17: p. 274]:

1. Technical: Can the system be implemented with current technology?
2. Economic: Do the benefits outweigh the costs?
3. Operational or Organizational (Political): Can the system be implemented in this organization?

Technical feasibility is well assured. Inventory control systems are not new, the data and reports required are well defined, and the DBMS products make the task less difficult.

Economic feasibility, as usual, is hard to quantify. How much is a 10 per cent increase in system accuracy worth to Navy planners responsible for ammunition procurement and allocation? Also, how much is the reduction in administrative burden, and the subsequent increase in operational readiness, worth? These are difficult questions to answer. In light of the relatively minor expense of the SAMS development however, it only makes sense to pursue an alternative to the present manual system. If the project progresses beyond the research stage to fleet implementation, the increased costs would warrant a more formalized cost-benefit study.

Political feasibility should pose no problems. Weapons and operations personnel on most Navy ships are already heavy users of computers in their daily routines. Any labor saving device, which reduces records as well, would most likely be welcomed.

B. ANALYSIS

The analysis phase of a project must fully determine what the system must do. How this is physically accomplished is the subject of the next section on design. For this author, the analysis phase began in 1983, unknowingly, with experience operating the manual system, which is largely unchanged today. However, under the pressure of multiple jobs, most users generally never acquire the big picture that is necessary to design an automated system. Normally the analyst will interview many people involved in different phases of the operation, plus review all the applicable documentation, to gain this big picture. This project required a slightly different approach. The author acted as an expert user/analyst and based on experience and intense study, the system was designed and partially implemented. The pitfall here is that the expert user is too "expert" to really appreciate user difficulties. These difficulties would have to be resolved by a period of "normal" user interaction in the fleet following complete implementation. It will be shown that a DBMS makes such modifications, as may be necessary to suit the bulk of the users, much easier to perform.

A complete knowledge of the existing system was the first major job in the SAMS development. Information, publications, instructions, reports, and forms were collected from all the commands and agencies involved in the flow of conventional ammunition to the fleet. The intent, policies, and procedures of the CAIMS program were studied to gain this big picture, even though many details did not directly affect the end user environment. There are several "layers" of instructions that deal with similar, or the same topics, and the semantic inconsistencies between these often necessitated phone call and extensive cross referencing to resolve. This overlapping of instructions is seen by this author as a definite problem. It can thwart a clear end user understanding of the system, since they have little time for phone calls or extensive research.

The object of SAMS is to automate the end-user inventory and control procedures while remaining compatible with requirements of higher level Navy instructions. External report formats must be as described in Chapter II, however internal stock cards would not be used in an automated system naturally. This would require modifications in those instructions deleting the requirements for those cards for the ships that are automated.

1. Data Flow Diagrams

One of the major tools of structured analysis is the use of graphical representations to depict information flow. Data Flow Diagrams (DFDs) are a network representation of a system which is generally much easier to understand, at least by the end-user, than the functional specifications of the past. The DFD is an analysis tool, and as such, is logical in nature and does not depend on hardware, software, data structure, or file organization. A logical representation is one that reflects a user's view of the system and its processes. Several references [Refs. 15,17: p. 60,281], give similar descriptions of the constituent parts and development of DFDs. Figure 3.1 shows the Fundamental System Model or the Context Diagram for the SAMS. This is the highest level of abstraction and shows the entire system as a single node. The user inputs data to the system or requests processing at the source square, the system node performs the necessary processing, and outputs data and/or reports at the sink square. This context diagram serves as a starting point but is not particularly useful or informative. Subsequent levels of refinement form a complete set of Data Flow Diagrams for the SAMS and are included as Appendix A.

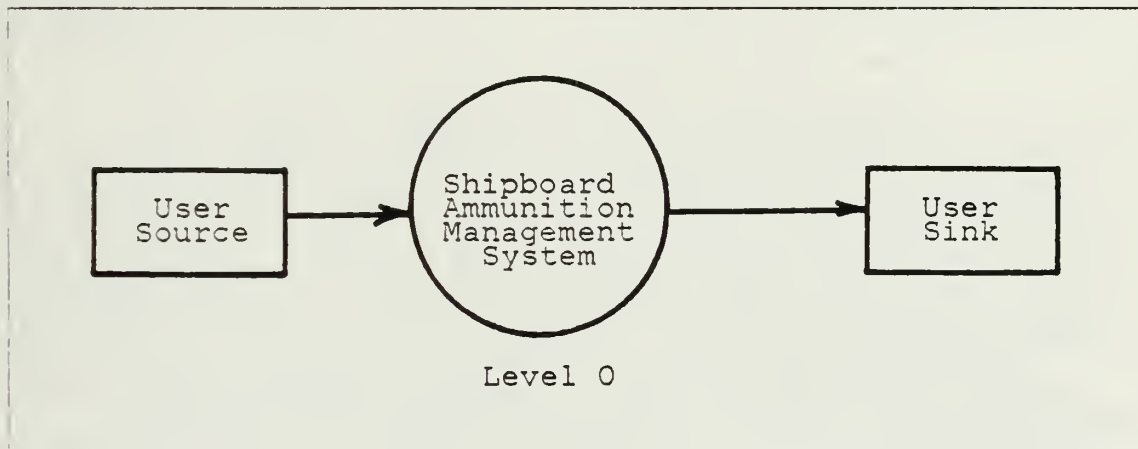

Figure 3.1 SAMS Context Diagram.

Data Flow Diagrams do not show flow of control or sequence of execution of the processes. Also, the representation of files are purely logical and may be implemented quite differently in the final design.

2. Subsystem Functional Description

Experience and research provided the logical divisions for the conventional ammunition management problem. Nine subfunctional areas were identified.

1. User Access Validation
2. General Information Documentation
3. Inventory Allowance Ammunition Data
4. Transaction Management
5. Requisition Management
6. Turn-in Document Management
7. NARS Management
8. System Management
9. Generate Internal Reports

This system breakdown seems obvious on the surface to anyone familiar with the manual system, as well it should be. The more closely an automated system follows the logical, or user's view, of the processes, the higher probability there is of the user feeling comfortable with the system. However, the system breakdown also considers the system goals and improvements desired in the automated system over the manual one.

a. User Access/Validation

The User Access/Validation function should ensure that only authorized users of the system may gain access. The SAMS is intended for use by Weapons Department personnel charged with the responsibility for ammunition, and as such, they should be the only people manipulating the system. Requests for system data from superiors can quickly be accessed by these people. The system should be capable of controlling authorized user's privileges within the system also. The SAMS only requires two basic levels of access. The lower level should allow access to the day-to-day processing options, two through seven and nine. The higher level will allow the SAMS administrator or manager to access all modules for system initialization, infrequent data changes, user changes, or to correct unforeseen system processing problems. This degree of power places great responsibility on the administrator and requires that he be fully knowledgeable of the system and the consequences of his actions. The risk in this approach is necessary however, because there will be no technical representative or outside help if the system develops a problem while at sea.

b. General Information/Documentation

The second option provides general information and documentation that the user may find useful in getting acquainted with the system. This may include a system description, explanation of the options available, what the system does not do, hardware requirements, basic keyboard operations, etc.. Also, this option should give the codes and definitions that are frequently used by the SAMS and within the CAIMS system as a whole. A data dictionary will not only explain the many acronyms but will increase the knowledge of the user and assist the manager in system management.

Finally, a help program can be resident within this option and called from various places throughout the application programs. It is very difficult however, to give adequate help to a user with generic help messages about a particular question he may have. The author feels that giving more, rather than less information in the user interface is generally less frustrating than needing to frequently use a help program. Now, if the program was in constant use by a dedicated operator the extra verbiage would become annoying, however that should not be the case here. The data entry to the SAMS would probably slow down an operator who has all of the many codes memorized, but for those less gifted (the majority), the system will minimize the time referencing manuals. Also, the instructive goal of the system can be more easily accomplished in this manner.

c. Inventory/Allowance/Ammunition Data

This is basically a review option. The user would frequently want to review the current status of his onboard inventory, perhaps with a quick overall perspective in mind or a detailed review of a particular item. The SAMS inventory information should make the present record cards unnecessary. Since the change in an inventory level can only occur as the result of a transaction of one kind or another, the inventory is not manipulated directly, but is updated as a result of transaction processing.

Allowance information can be conveniently stored in the system where training expenditures can be updated and monitored. Again, any update occurs as a result of transaction processing.

Ammunition data is that generic information about a particular item that does not change as a result of transactions and previously would have been looked up in one of several publications. See references 12 and 14 for examples. Any amount of information, about any kind of ammunition, could be loaded into the system, however to save disk space, only those items the particular ship would likely carry should be entered. The system manager can add or delete items as necessary.

d. Transactions

Transaction Management is the major processing function of the system. A unit can receive items through a receipt, condition code change, or a few other infrequent occurrences. It can reduce stock by an issue, expenditure, condition code change, or other reason. This subsystem should recognize the type of transaction, update inventories, create the information that will go on the ATR, and update other files when necessary. For example, a receipt transaction should update the requisition file if the receipt occurred as a result of a requisition the ship submitted. An expenditure transaction should update the Allowance File if that item had a training allowance.

e. Requisitions

Requisition Management involves the creation of requisition documents in the various allowable formats. The MILSTRIP system, discussed earlier, is heavily code oriented, and this option should guide the user through the selection of the proper codes for the particular item at hand. This module should also store the information as a permanent record, eliminating the need for manual records. A user may edit these records during creation and prior to their being submitted, however the integrity of the data would be violated if he were allowed to do so afterward. Therefore, as with ATR's and Turn-in documents, there is a point where the data must be committed, and not changeable by the user. Any special cases could only be adjusted by the system manager.

f. Turn-in Documents

The Turn-in Document Management function must create and store the turn-in record and print the DD Form 1348-1, the Single Line Item Release Receipt Document. The processes involved are very much like the requisition management function: one representing imminent issue and one representing imminent receipt. Later, when the transaction actually occurs, an issue transaction can be processed which updates the inventory. Naturally, the information already recorded by the Turn-in processing need not be collected again, rather the Turn-in file is linked to the Transaction file and the information transferred.

g. NAR Messages

Naval Ammunition Reclassification (NAR) Management serves to process these messages as they are received. A stock check must be conducted to determine if the ship holds any of the ammunition lots specified in the message. If the check is negative, the only action required is to log the serial number of the NAR message. If

the stock check shows that action is required, then the proper reclassification transaction must be processed. The information pertinent to the NAR must also be saved for future reference and historical records. There should also be a link between a reclassification transaction and the NAR message that precipitated it.

h. System Management

The System Management module will be extremely powerful, allowing the manager to globally edit all files and initialize the system. He will also be able to manage the security system, archive old records, recover the system when necessary from backup files, and have access to the operating system and DBMS dot prompt. System documentation, of no real value to the normal user, will be available to the manager, to further his understanding of the system.

i. Internal Reports

Lastly, the Generate Internal Reports function will produce those reports that the typical users, and their supervisors, would find useful in management of their conventional ammunition program. Of course, the information would also be available on-line, but it is often useful to have hard-copies. Microcomputers will still not fit in one's back pocket! The SAMS should be flexible enough to allow future report requirements to be incorporated without system redesign. The data flow diagram for this function describes several of the anticipated reports, however expansion is probable as new requirements come to light. User experience would suggest other useful reports.

3. System Data

As the name would suggest, a data flow diagram shows the data that interfaces the active processing areas of the system. The data is stored in files for later recall or processing. A convenient way to aid the analysis of a system is to identify the data that is require at the "sink" and work backwards through the system to the source of the data. The SAMS has certain data elements that it must be able to produce to construct ATRs, requisitions, and turn-in documents. Also, it must record the inventory data to replace the manual stock cards. This data then forms the minimum set for the system. Table 2 identifies the data that is included in these output documents and the stock cards.

These data elements thus form the initial inputs to a Data Element Dictionary (DED). A DED is basically a collection of data about data. The idea is to provide information on the definition, structure, and use of each data element in the system

[Ref. 17: p. 296]. Table 3 lists the format of the information that will be stored in the DED for each data element. By exactly defining the meaning and structure of the data elements, standardization among the application programs is facilitated. Also, as will be discussed, relationships between data can be utilized to greatly increase the amount of useful information the system can produce. This can only be accomplished if consistent data definitions are observed. The DED for the SAMS will be an on-line

facility for user reference and may also be printed for hard copy documentation. Appendix B is the SAMS Data Element Dictionary.

C. DATA ORGANIZATION

1. File Processing

A final consideration, and one of primary importance, is the manner in which the system's data is stored and represented. Traditionally, file processing systems organize all of the data for a particular specialized application into a single file and the program operates on that file to produce the output. In this manner, the file is really just a storage medium for potentially very dissimilar data. No data organization is implied other than sequencing. Other specialized application programs would operate on files that contain all of the data necessary for that application. In terms of the SAMS, such a system might be structured as in Figure 3.2 .

There are some immediate problems with this method of file and data organization for an ammunition management system. First, since each file contains all of the data needed for it's program, there is much redundant data in the system. This of course requires much redundant data entry which the operator resents because he logically questions the necessity for doing it. For example, each of the files in Figure 3.2 , and their associated program, require the name of the ship producing the documents, and thus the files must contain that data. This type of redundancy has traditionally been accepted because the programs that would be required to share data among files were complex. Unless all the application programs and files are constructed with compatibility in mind, a conversion process between different record formats might be necessary. A one-of-a-kind request necessitating shared data would have to be vitally important to merit such effort.

This lack of integration capability limits the information that can be obtained from the data. However, the redundancy of data also presents problems other than the multiple data entry required. It wastes storage space in the files, which is important when considering a microcomputer application. The larger files also cause slower processing times for the system as a whole. Finally, when data elements change, the different programs must all be updated or inconsistencies will result.

2. Database Processing

Database processing is quickly gaining ground on file processing in most ADP applications and has several major advantages over file processing techniques. First and foremost, Data Base Management Systems (DBMS) allow the sharing of data

TABLE 3
DATA ELEMENT DICTIONARY FORMAT

Longtitle:	The long title of the data element. It may contain up to 30 characters.
Name:	A short hand version of the long title to be used in programming and is compatible with the DBMS variable representation and length for record and field names. (10 characters for field names and 8 characters for record names.)
DEN:	(Data Element Number) For those data elements that are cataloged in the Standard Data Element Dictionary(SDED), a DEN is assigned. The DEN consists of an alphanumeric character followed by three or four numerics. The DEN acts as a means for controlling data elements and as a short hand name.
Picture:	The data type of the element, i.e. character, numeric, logical, etc., and the width of the field.
Desc.:	The narrative description explains what data or information the element represents.
Refs.:	Publications and other documentation that give additional information about the data element.
Codes:	If the data element has codes associated with it, the reference that lists all those codes and their meanings is given. (Most codes are given in the General Information option 1.)
Used in:	All relations in which the data element appears. (SAMS Relations)

Figure 3.2 File Processing System for SAMS.

between files quickly and easily. This is accomplished by the DBMS program itself, which is usually quite complex, but fortunately requires the user to know nothing about its intricacy. Thus the system files are established under DBMS control in a compatible format. Application programs only communicate with the DBMS, as far as data retrieval is concerned, and it "fetches" the desired data by its own means. Sharing data means that a reduction in redundant data is now possible through intelligent file design. In contrast to Figure 3.2, Figure 3.3 is a representation of how the SAMS might be constructed using database technology.

A DBMS also creates program/data independence since the programs do not need to know anything about the data structure of the files. We can add application programs that use any of the files and this gives much flexibility in system design. Fields can even be added or deleted from the files without any effect on the programs that do not explicitly use the affected data.

There are some disadvantages to database systems, however for medium-to-small applications, with much interaction, they are very insignificant [Ref. 18: p. 6].

The SAMS will therefore use a modern commercial database package, dBase III Plus, by Ashton-Tate of Torrance, California. This is a moderately priced package for use on microcomputers and has gained much popularity. dBase III Plus is a relational database which simply means that data is represented in the form of tables, or relations. Readers interested in a full discussion of relational database theory should refer to Date [Ref. 19], Ullman [Ref. 20], Kroenke [Ref. 18], and Brodie [Ref. 21].

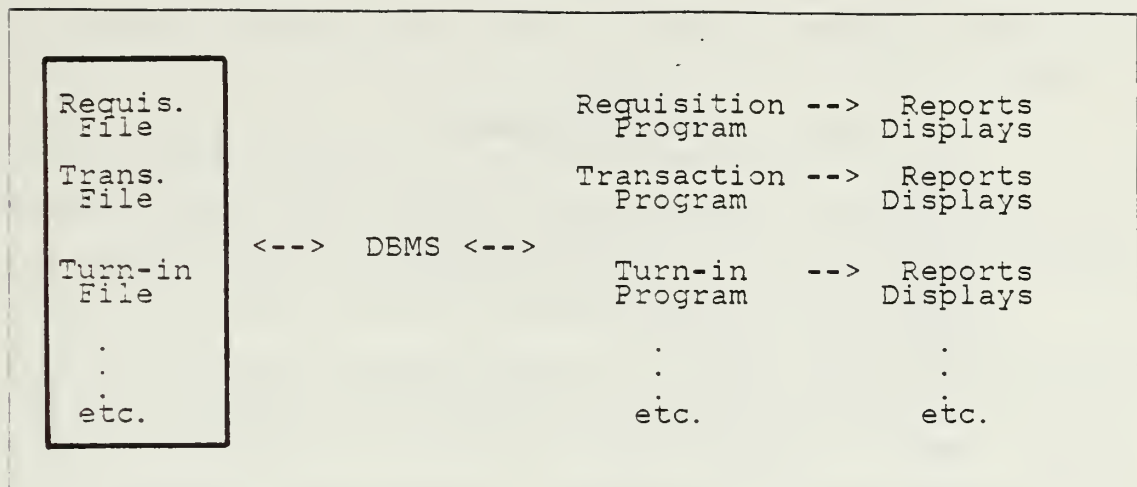

Figure 3.3 Database System for SAMS.

It was previously mentioned that a reduction in redundant data was possible through intelligent file, or relation design. Good design consists of properly matching the data elements, or attributes, of a relation so as to prevent data integrity problems. Wetherbe and Dickson [Ref. 22: p. 213] describe the common integrity problems as:

1. Difficulty in accurately identifying, locating, or updating all records given a specific set of attributes.
2. Needlessly repeating fields in records, therefore requiring redundant storage and updates.
3. Inconsistencies among data.
4. No records within which to store certain fields.

The process of normalization is a set of rules or guidelines which help a database designer build relations that minimize update anomalies and data inconsistencies. For larger systems with a high transaction rate, strict compliance with all of the normalization rules can lead to conflict with retrieval performance because normalization generally results in more relations. This then requires more effort to retrieve all the necessary data. The SAMS however, will be a relatively small system with a low transaction rate, and therefore the design should strive for maximum reasonable normalization. Excellent descriptions and examples of the normalization rules are given in Kroenke [Ref. 18: p. 286] and Kent [Ref. 23].

There are seven normal forms identified, and in consideration of the type of data involved in the SAMS, it may be difficult to apply higher than the Boyce-Codd

normal form (BCNF) in most cases. Briefly, the guidelines, or rules up to this point are:

1. All records in a relation must contain the same number of fields and none must repeat. This is basically the definition of a relation in relational database theory.
2. The second normal form requires that all non-key attributes are dependent on the key. A key is one or more attributes that determine a record.
3. Third normal form is satisfied when no non-key attribute provides a fact about another non-key attribute.
4. Boyce-Codd normal form requires that every attribute that provides a fact about another attribute (determinant), must be capable of being a key for the relation (i.e. a candidate key).

Thus, analysis concludes with the generation of DFDs, the functional descriptions, identification of the data and it's structure, and consideration of the normalization policies for the database relations.

IV. SAMS DESIGN

The design of the database relations for the SAMS is a critical juncture in the development process. For the reasons discussed in the previous chapter, thoughtful design of these relations will ensure the flexibility and integrity of the system.

Relation design is not an easy task, even for a relatively small system like SAMS with only a hundred or so data elements. A starting point is to logically group data elements as was done for the external reports and stock records in Table 2 . We must also then consider the data elements that deal with generic ammunition information, allowance lists, NAR messages, addresses of other Navy units, and constant data referring to a particular ship (static data). If we assemble these lists independently of each other, there is much data duplication which must be minimized for the normalization we require.

To store data elements in one relation, yet link them to other relations, there must be common attributes between the two relations. However, these attributes must be unique so that the DBMS can locate the correct record. This normally requires that the relationship be established to a key attribute. DBase III Plus requires that the attribute that is being searched for be an "index" of the relation. An index is a file that is created for an associated database relation which contains a particular attribute in alphabetical, or alphanumeric order and its associated record number in the database. This allows the DBMS to quickly search for a particular value of an attribute in the index file and obtain the corresponding record number in the database file. When records are added or deleted from a relation, only the indexes are reorganized which could save considerable time in a large database. Moreover, many indexes can exist, on different attributes, for the same relation.

With these considerations in mind, the SAMS data elements are separated into appropriate relations and indexed as deemed appropriate to accomplish the file relationships desired. The relation structures will be fully described with regard to normalization in the next section.

Although compatibility in data elements or software is not required of the SAMS, as it is a stand alone system, it was desired that data elements used in the CAIMS be used by SAMS where possible. This resemblance would minimize any

difficulties in user understanding when referring to supply system or CAIMS publications. Also, since CAIMS already has a Data Element Dictionary (SDED), it is a question of not "reinventing the wheel". If data elements in this dictionary were directly applicable to the SAMS, they were used. Minor modifications in data element name or picture were necessary in some cases (COBOL vs. dBase III Plus), but the meanings were close enough to assign the CAIMS Data Element Number (DEN) to the SAMS element.

Table 4 lists the conventions used in selecting the SAMS database and index names. It is easy to see that some sort of pattern is necessary in selecting file names, their number quickly grows beyond human memory. Table 5 conveniently lists the database files and their associated index and format files. A format file is constructed by the DBMS, with user interaction, to create custom data entry screens. Even this relatively small system is composed of over fifty programs and fifty files, therefore program and file directories are also needed. A complete program directory is included as Appendix C.

A. SAMS PHYSICAL RELATION DESCRIPTION

Table 6 lists the physical structure for all of the SAMS database files. It would be helpful to the reader to refer to this table throughout this discussion.

1. Transaction File (ATR File)

This file contains the data elements that relate specifically to a particular transaction. The key in this file is the ATR serial number (ATRSERIAL). To normalize to the Boyce-Codd Normal Form (BCNF), every determinant must be a candidate key, and the only key here is the ATR serial number. Every other data element should furnish a fact about the key, and only the key, and this is satisfied with one exception mentioned later.

As mentioned in Chapter II, ATR numbers run from 001 to 999 and then repeat. It would take quite a few years for the typical ship to go through 999 numbers. Repeating key elements can not be permitted so if there was a chance of this, the old records would be archived. Old instructions required that ships restart their ATR numbers when "chopping" (Change of Operational Command) to another fleet. If this situation existed on a ship that SAMS was to be installed, the old fleet numbering sequence should not be included in the initialization to prevent repeating key field values.

TABLE 4

The ATR Status is a local SAMS data element which serves to indicate the condition of a particular record. A transaction can be incomplete, ready for submission, or submitted. An "incomplete transaction" is one in which the user has not completed entering the necessary data or he is not ready to say the data is correct. This is strictly a user assigned status and no inventory update takes place based on an incomplete or blank entry. When the user is satisfied that the data is correct, he changes the status to "ready for submission", and inventory update takes place. At this point he may print the ATR for submission to the Radio Room or Communications Center, however he may not edit or delete the record. When the message is routed back from the communications personnel, verifying broadcast, the status can be changed to "submitted", and the message Date Time Group (DTG) entered. The DTG may be used on subsequent ATRs and thus must be retained.

The National-Item-Identification-Number (NIIN) uniquely identifies a type of ammunition and can therefore be the link to the Ammunition Data file to obtain the Type of Maintenance Due Code (TMDC). The TMDC will be required on ATRs that involve Serial/Lot Item Tracking (SLIT) material.

To uniquely identify an ammunition item that is or was physically in the ship's inventory, not only the NIIN, but the Condition Code (CC), Activity Classification Code (ACC), Lot Number, and Component Serial Numbers (if applicable), are required. Multiple items with serial numbers can be included on one ATR, so up to ten serial numbers may be included in this record. Unfortunately, in one regard, variable

record lengths are not defined in a relational data base system, so some storage space will be wasted because most transactions do not involve items with serial numbers. Only rarely would a transaction involve more than ten serial numbers. In this case, a second transaction report could be prepared.

The ATR Julian Date (ATRJULDAT) is the three-digit julian day of the year that the ATR is prepared and appears in the header line of the message. It will not necessarily be the same as the message DTG.

The beginning and ending balance must be maintained in the Transaction file because the Inventory file is dynamic in nature having the "instantaneous" stock levels. Thus the Transaction file is the historical record of stock levels.

Quantity seems an obvious data element in the ATR, however if the transaction is a receipt or issue, the document number of the associated receipt or turn-in document is also included. This case would violate the Third normal form because quantity is part of these documents. However, Quantity must be included because expenditure transactions have no corresponding document.

The User Source Identification Code (IDCODE) is a similar situation. For receipts and issues the IDCODE would be the "ship to" or "received from" on the shipping document, however in other cases it can take on other values. Thus it must be included as part of the record.

Finally, any narrative message (ATRREMARKS) must be saved and this is naturally the only place to do that.

The preceding description of the Transaction file and its structure may have seemed rather tedious, however the reader should take heart that commonalities in the other files will not be repeated.

2. Requisition File

Serial number and julian date uniquely identify the requisition, while the other two components of a requisition document number are accessed from the Static Data file. The NIIN again uniquely identifies the item that is being ordered.

The requisitionee and supplemental address UIC and service codes are included in the requisition file. Ninety per cent of the time, an activity's UIC will determine its service designator code, however if that activity is a ship and it changes fleets, then its service designator code will change. The supplemental address is normally the activity at which the material will be received, or loadout activity.

Requisition Status (REQUISSTAT) serves a similar purpose to that in the ATR file except that it must also be able to represent partially filled and cancelled requisitions.

The remaining data elements are multi-valued codes which are all independent and describe the circumstances of the requisition, urgency of need, required delivery

date, etc.. See Appendix B, the Data Element Dictionary, for a complete description of these items. This file also satisfies the Boyce-Codd Normal Form.

3. Turn-in File

The turn-in file may seem to be a redundant file in itself because it will eventually represent a turn-in transaction (issue transaction). However, two considerations help to clarify the need for the file. First, a turn-in document may be prepared well ahead of the actual transaction date and the timing of the inventory update would become a problem. Certainly the inventory should not be updated until the physical stock levels change. Secondly, a turn-in document requires three or four data items that are not needed on a transaction report and thus the ATR file would be made needlessly larger just to accomodate these items.

The turn-in file record must be able to uniquely identify an item of inventory, just as the ATR file must. Therefore the same five data elements: NIIN, ACC, CC, lot number, and serial number(s), must be included to accomplish this.

The ATR serial number is provided to link the record to the transaction record in the ATR file. This data would be automatically appended to the record when the transaction document was prepared.

Finally, a link to the NAR Action file is necessary if the turn-in is in response to a NAR message. The NAR Serial member and the NAR Year accomplish this.

4. Ammunition Data

This file contains data elements that provide facts about specific items (types) of ammunition. The unique element is of course NIIN. This file essentially replaces the need to reference two or three large publications and is accessed many times in the application programs. The Data Element Dictionary, Appendix B, contains complete explanations of these independent descriptors.

One "confusion factor" still remains however. Although NIIN reporting, vice NALC reporting, is logical and consistent with good inventory control, NALC is still used as an identifier in NAR messages, allowance lists, and other documents. For years, NALC has been the defacto unique identifier of ammunition items, and until all organizations begin using NIIN as such, the Ammunition Data file will serve as the NAR-to-NIIN converter in application programs.

It is questionable if the NALC in this relation could be considered a candidate key. Many of the data elements realistically do provide a fact about the NALC, a non-key field, so the Third Normal Form would be violated. This seems unavoidable in this case however.

5. Inventory File

This file is suprisingly simple. The five identifiers of an individual item are there along with the MDD which will be associated with serial number controlled items. If the item is serial number or lot serial number controlled (MCC "C" or MCC "E"), the quantity for the record will be one. Items that are only lot controlled or have no MCC will have a quantity that reflects all the items in the lot. This relation has such a large key (five data elements), that there are only two others that are not included, quantity and storage location. Boyce-Codd Normal Form is easy to attain in this case.

6. NAR Action File

This file contains reclassification data from a NAR message that affects inventory held on board. Only those NARs that are applicable are entered here. The NAR Serial File records all NAR messages received so that any missed messages can be noted.

Naval Ammunition Reclassification messages identify affected ammunition by NALC, lot number, and sometimes serial number. Since lot numbers are not necessarily unique, and a NALC may contain several NIINs, we must first determine the NIINs associated with a particular NALC. The inventory can then be searched for those NIINs, which are a key element of the Inventory file as well as an index. Upon locating an applicable NIIN, the lot number is compared with that contained in the NAR message. This procedure would be much simplified if NAR messages used NIIN as the identifier.

The NAR Action File also contains the ATR Serial Number which took the action the NAR called for. This would be automatically appended when a reclassification ATR was processed.

Finally, this file contains a character field to record the reason for reclassification, which is normally included in the message itself. Also a field, TAGLABEL, to record the label or tag that must be attached to the actual ammunition to explain it's status. This label would be a statement like, "For Training Use Only", or "For Emergency Combat Use Only".

7. NAR Serial File

This file's purpose is to provide a convenient location to record all the NAR messages received, whether applicable or not. This method allows the NAR Action File to be much smaller, since non-applicable NARs are excluded. Thus we minimize the size of a relation with nineteen fields by creating one with only three. This file is in Fifth Normal Form, which means that it is in BCNF and it contains no transitive dependencies (fourth), and it can not be subdivided in any way.

8. Allowances File

This file contains the authorized types of ammunition and quantities that a ship may carry. Allowance Lists, promulgated by the Naval Sea Systems Command (NAVSEA), again use the NALC as an ammunition identifier [Ref. 3: Chapter 7]. Remembering that the various NIINs within a NALC group are functionally equivalent, it is clear why NAVSEA publishes the lists in this manner. A ship may carry any NIIN item within the NALC group to satisfy the Allowance List requirements.

The inclusion of the Activity Classification Code (ACC) in the Allowance file allows ammunition for other end uses to be shown in this file rather than creating a different file for each ACC material carried onboard.

Finally, this file contains a computed quantity, USED FY, which will be automatically updated during expenditure ATR processing to show the quantity of ammunition, which has a training allowance, that has been used in the fiscal year. The system manager will need to reinitialize this quantity each year. Performing the computation at this time and storing the value is a departure from strict normalization, however it is far more efficient than doing all of the calculations just prior to printing a training expenditure report.

9. Address File

The Address file contains pertinent data about other supply activities and commands with which a ship may conduct ammunition business. The UIC and Activity Name (ACTIVNAME) are both candidate keys, however UIC is less easily confused than two similar names and it is also only five characters. This makes it better as an index, decreasing search time. There are transitive dependencies in this file; Activity Name and Location can determine Service Designator Code, however Boyce-Codd Normal Form is still attained.

10. Static Data File

This file is unique in that it only contains one record, namely data about the ship that the SAMS is installed in. It furnishes information to application programs that need the ship's name, hull number, etc. to print documents and reports. The Fund Code is needed on requisitions and the Monitoring Activity (MONITACTIV) is combined with the Cognizance Symbol to form the Distribution Code, used on several documents.

The remaining database files are for system documentation and will not affect the operational performance of the system.

B. SAMS STRUCTURE CHARTS

The last step in the design stage is to determine how the system will be partitioned into modules, or programs. These programs will operate on the database relations, via the DBMS, and interactively with the user to perform their function. Unlike a Data Flow Diagram (DFD), the structure chart presents system hierarchy, control, and communication. Appendix D presents the SAMS structure charts.

Structured design has several measures with which to gauge the quality of a system's structure chart. The first is coupling, which is the degree of independence between modules, and the objective is to minimize this. The second is cohesion, which evaluates how closely the activities within a module relate to one another. A module should be considered a "block box", in that it performs its designated function with the surrounding modules knowing little or nothing about its internal code. [Ref. 15: p. 101,117]

A database management system tends to make structured module design an easier process than in the past. The problems of data storage are removed from the application programs and handled by the DBMS. thus traditional input/output modules are not necessary. This fact allows programs to flow from one logical process to another without the traditional housekeeping chores. Previously, structured design techniques responded to this by making modules very small with single cohesive functions. A DBMS with a good programming language can produce programs that remain understandable and cohesive while allowing a chain of logical thoughts to be contained in one program.

The SAMS is menu-drive when the selections are unambiguous, and almost conversational when the selections require a more detailed knowledge. Referring to the

Structure charts provide the programmer with a framework for the implementation of the various subsystems and individual modules, while the Data Flow Diagrams provide a guide to the logical processes of the subsystems. Neither graphical representation should be regarded as "cast in concrete" however, the physical implementation may suggest modifications.

V. IMPLEMENTATION

A. IMPLEMENTATION PROGRESS TO DATE

Early in the development of the SAMS, it was obvious that complete implementation and field testing would be quite impossible in the available research time. Therefore the author selected the portions of the implementation that would be the most beneficial to anyone continuing the effort, and provide a framework for that implementation.

The design stage identified all of the programs necessary for the SAMS. They are listed in the PROGFILE database and may be printed with their associated data by running PROGFILE.prg. Appendix C contains this listing. Approximately one quarter of the systems programs have been implemented.

The Requisition Management subsystem was fully implemented because it's programs demonstrate a myriad of programming techniques to accomplish their tasks. There are modules to review databases, edit/delete, create documents, print documents, backup files, and various forms of interactive programming are demonstrated. Most of the other SAMS subsystems use many of these processes, so a close review of the Requisition Management programs can significantly decrease the learning curve for future programmers. Completed program listings are contained in Appendix E.

In addition, the database, index, and format files necessary to operate the Requisition Management subsystem were created and loaded with sample data. Testing was performed throughout the implementation of these modules to show correct operation, although not exhaustive or as a dedicated separate evolution. System testing is obviously a critical phase of the development process not to be slighted. Module independence will greatly facilitate testing and make rapid debugging possible.

Many of the system documentation modules were also completed during the analysis and design stages and should greatly assist future programmers. These include the Data Element Dictionary, structure charts, program files, files directory, and cross reference between programs and relations.

B. CODING STYLE

Without repeating at length the ideas that have been presented throughout this paper concerning the interactive style of the SAMS, it might be worthwhile to bring together in one spot the essential points.

First, SAMS must be easy to use. Although larger ships may be able to dedicate a single person to the responsibility for system operation as a primary duty, this will normally not be the case. Therefore the slant should be toward more information, rather than less, in the interactive process. This assumes the operator will not be so familiar with the system that the extra information will be annoying. The Requisition Management option presents the user with most of the information that could be gleaned from several publications. The difference is that the publications contain a whole range of logistics information, and the SAMS will present pertinent information that fleet users need and no more. Therefore, the key phrase is "complete, selective information".

The system administrator, or manager, must be knowledgeable of the instructions and publications that explain the present system, and the operators must have a working knowledge. The manager should understand the basics of dBase III Plus, not to the degree of being able to program, but enough to be able manipulate relations should a problem arise. Moreover, he should understand the implications of his ability to alter those relations.

Finally, code documentation should primarily be contained within the listing itself. Placing it here will increase the chances of it being useful to a future maintenance programmer, and it will be easier to maintain of its own accord. Some authors feel that source code comments are perhaps the easiest form of documentation to maintain, [Ref. 17: p. 251 and 341], and this author would tend to agree.

VI. CONCLUSIONS AND RECOMMENDATIONS

The Shipboard Ammunition Management System presented in this thesis is one viable alternative to the present system. It automates much of the manual record keeping, can prepare useful management reports, and produce external documents compatible with the supply system's ADP equipment.

There are several factors that make a stand alone system difficult to design. First, it must be compatible with different processing systems. It must automate manual procedures on one hand and on the other hand it must produce documents that are compatible with machine readable capabilities of the shore establishment. This dichotomy has in part been a reason why the system has been getting more difficult for the "customer", the fleet user, to maintain. Machine readable ATR's may eliminate key punching errors at the SPCC level, however they are incomprehensible at the user level except to the preparer. Every message that leaves a ship should be checked for accuracy by at least two people prior to the commanding officer signing his permission to transmit, and this could run into considerable manhours if everyone must dig through publications to look up "funny codes and formats".

Thus, a second alternative to solve the problem is to extend automation capabilities to all ships from the shore based ammunition management systems. A unified system, with one set of rules, would definitely be superior to a fragmented system. The professional managers of ammunition ashore would then be able to extend their expertise to the fleet, in order to allow the professional users of the ammunition to practice that more, and management less.

A second problem, as this author perceives it, is the overlapping of directives between the supply system and the fleet logistics agents. The fleet user should deal with one set of rules, perferably one definitive reference. For example, in the Pacific Fleet, a submarine weapons officer has three levels of guidance concerning conventional ammunition management [Refs. 3,4] and operational force commander instructions. Now, there may be good reasons for modifications depending on the theatre of operations or weapon type, but the users guidance should come from one place, to minimize confusion. Consistently following this policy would probably reduce by one third the number of publications that a typical ship is required to carry, in weight if not in number.

The Shipboard Non-tactical ADP System (SNAP) is currently being installed on Navy ships in increasing numbers and is designed to handle many supply, maintenance, and administrative functions previously done manually. This could provide an excellent vehicle to automate the ammunition management function. This thesis and others could provide functional, if not design descriptions of such a subsystem to SNAP.

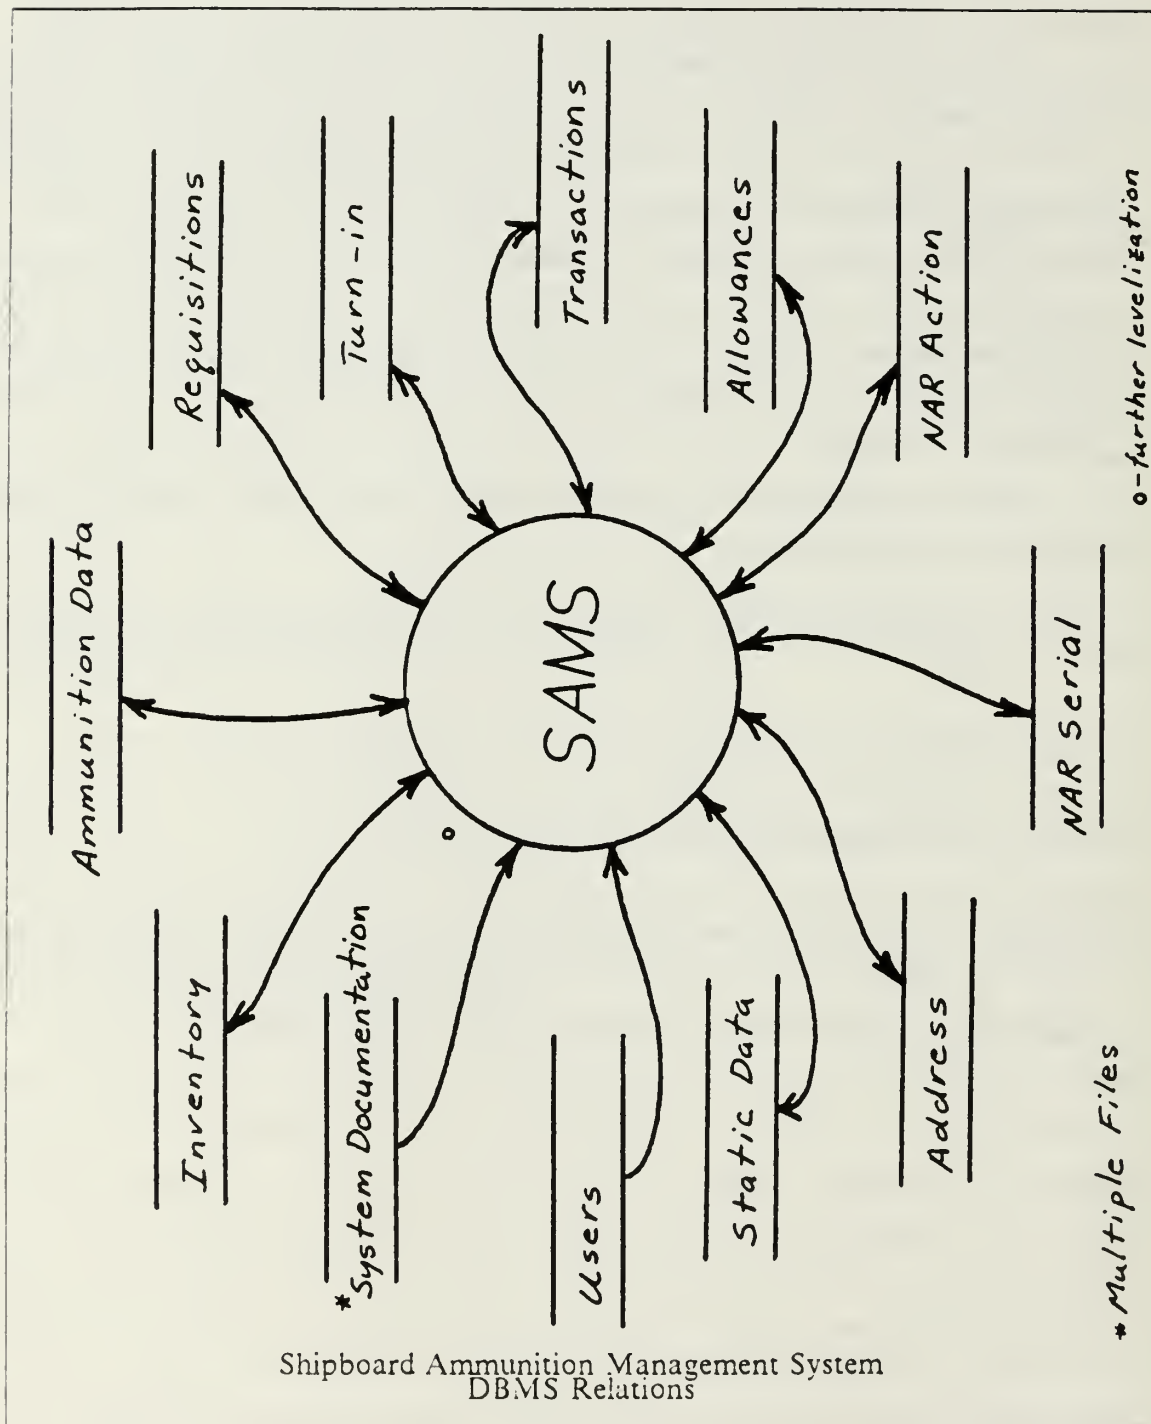

Finally, if the preceeding alternatives can not be economically or politically justified, then a stand alone system, the SAMS, should be pursued. The author estimates two to four months of programming would complete the SAMS application programs, then a pilot ship should be selected for the initial installation. The SAMS should run in parallel with the existing manual system to gather user experience, document "bugs", and adjust user interface. This phase would be an extremely interesting follow-on thesis in itself. Ultimately there must be a program office for the SAMS, logically as part of CAIMS at SPCC, to provide guidance and installation assistance to the fleet.

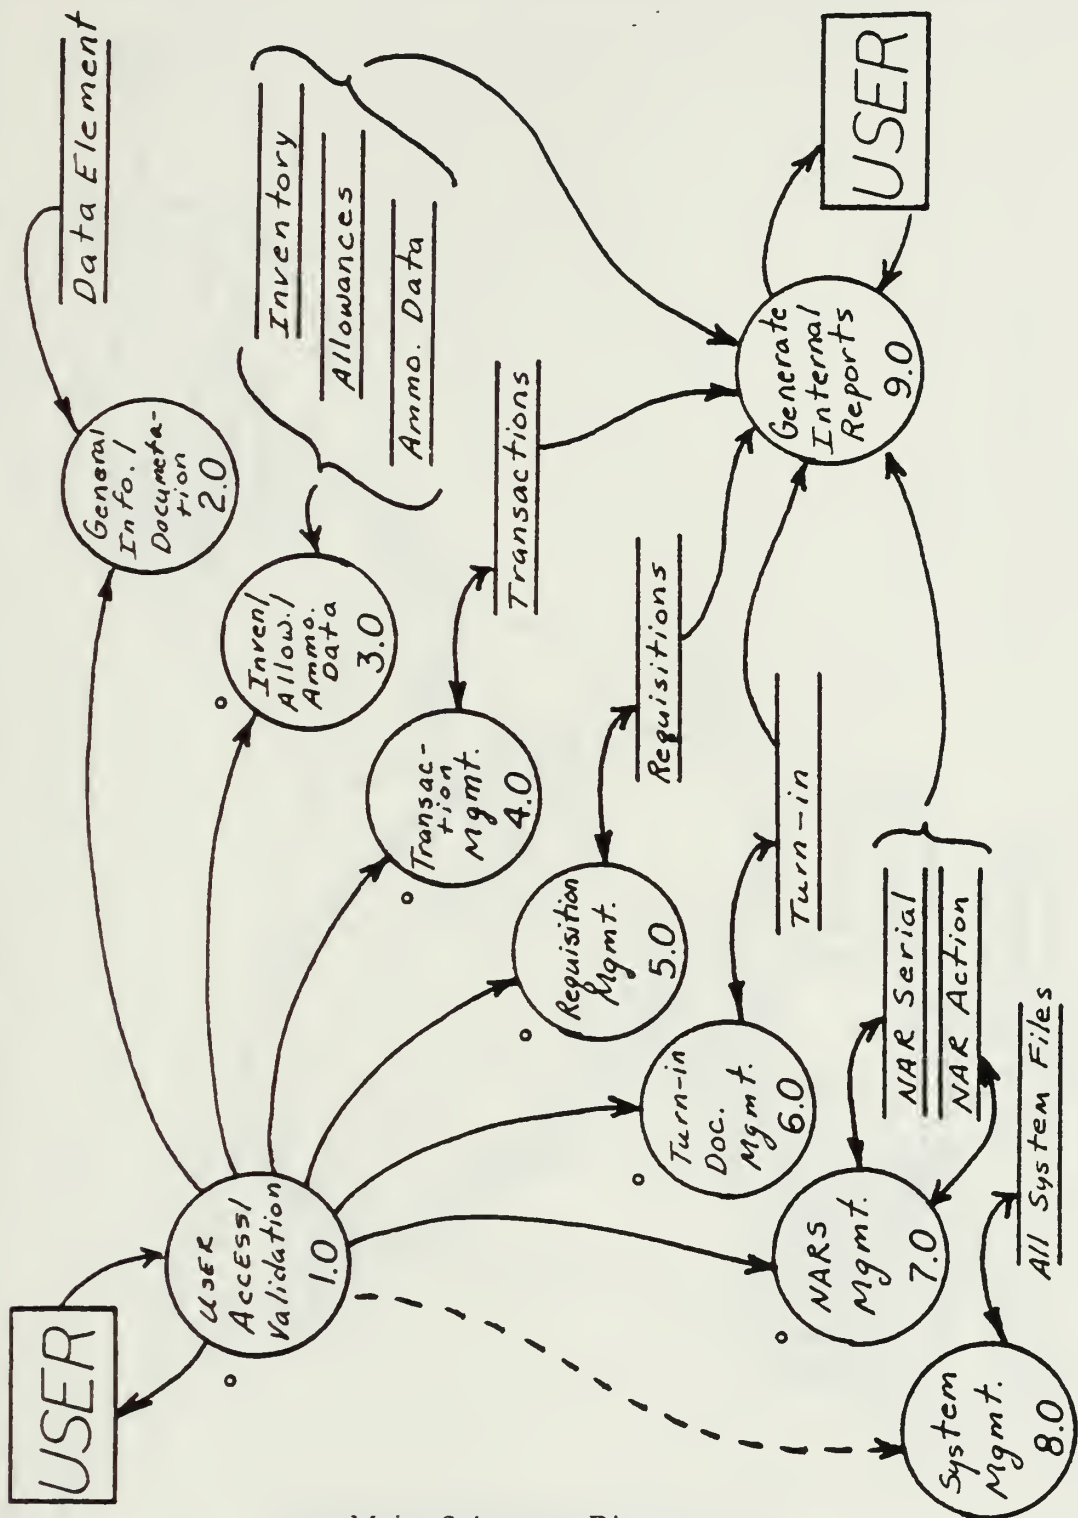

Therefore, the problems of conventional ammunition management can be handled in one of three ways:

1. An automated system within the CAIMS from SPCC down to all shipboard users.
2. Inclusion of ammunition management in SNAP.
3. Stand alone ammunition management - SAMS

The goal in selecting any one of the three is to improve and unify the system, and to reduce the administrative burden on shipboard personnel. The status quo will not be suitable in the long term if we desire an increase in fleet readiness.

PIC: X(5)
DESC: Quantity in per unit-of-issue amounts. For quantities greater than 99999, use an M in the rightmost digit to indicate thousands. Normally all positions should be filled in, including leading zeros.

USED IN: AMREQUIS, AMINVEN, AMTURNIN, AMTRANS, AMALLOW
REFS:

DEN:
NAME: REFERENCE
LONG TITLE: Data Element References
PIC: X(70)
DESC: The Navy or Supply publications which fully describe
the purpose and use of a data element.
USED IN: DATAELEM
REFS:

DEN: K018
NAME: REQDELDATE
LONG TITLE: Required Delivery Date
PIC: 999
DESC: When used on a requisition, this element consists of
a three-digit julian date which indicates the date
that the material is required by the requisitionee.
USED IN: AMREQUIS
REFS:

DEN:
NAME: REQUISSTAT
LONG TITLE: Requisition Status (SAMS local data element)
PIC: X(A)
DESC: A local system code to indicate the status of a
requisition action, ex.incomplete, ready,
submitted-not-filled, etc.
USED IN: AMREQUIS
REFS:

DEN: A001
NAME: ROUTIDENT
LONG TITLE: Activity Routing Identifier
PIC: X(3)
DESC: A three digit alphanumeric or alphabetic code
assigned to Inventory Control Point, Inventory
Managers, Distribution Points, and designated storage
points. Used to indicate the intended recipient, the
actual shipper, or action orig. activity
USED IN: AMDADDR
REFS:

DEN: C017
NAME: SECRISKCOD
LONG TITLE: Security Classification Code
PIC: X
DESC: This code designates the degree of physical security
assigned to an item of supply.
USED IN: AMMODATA
REFS:

DEN: K048
NAME: SENDTOSERC
LONG TITLE: Service Designator Code (of requisitionee)
PIC: X
DESC: Service Designator Code of requisitionee, PAC, LANT,
etc.. A code that identifies a service or element of
a service.
USED IN: AMREQUIS
REFS: (a),(b),(c),(d)

DEN: A002
NAME: SENDTOUIC
LONG TITLE: Unit Identification Code of requisitionee

PIC: X(5)
DESC: UIC of requisitionee. Identifies a ship or shore activity uniquely in the manner specified by individual military services for accounting and other purposes.
USED IN: AMREQUIS
REFS: (a),(b)

DEN: K002C
NAME: SERIAL
LONG TITLE: Requisition/Turn-in Serial Number
PIC: 9(4)
DESC: The portion of the Document Number (DEN K002) which applies to the serial number of the document. Under CAIMS, ships use sequential numbers 8000-8999 and then repeat when necessary.
USED IN: AMREQUIS,AMTURNIN
REFS: (a),(b),(c)

DEN: D330
NAME: SERNUMBER
LONG TITLE: Component Serial Number
PIC: X(16)
DESC: An identification number given to each item manufactured within a particular lot of a given stock number.
USED IN: AMINVEN
REFS:

DEN: K048
NAME: SERVCODE
LONG TITLE: Service Code
PIC: X
DESC: A code that identifies a service or element of a service.
USED IN: AMDADDR,AMSTDATA
REFS:

DEN: A002
NAME: SHIPTOUC
LONG TITLE: Unit Identification Code of receiving activity
PIC: X(5)
DESC: Identifies a ship, shore activity, operational unit, agency, contractor, or other organized entity in the manner specified by the individual military service/agency for accounting or other purposes.
USED IN: AMTURNIN
REFS:

DEN:
NAME: SHORTTITLE
LONG TITLE: Short Title of ammunition item (SAMS data element)
PIC: X(20)
DESC: Short description of ammunition item for quick reference.
USED IN: AMMODATA
REFS:

DEN: K021
NAME: SIGNALCODE
LONG TITLE: Signal Code
PIC: X(A)
DESC: This code designates the fields (card columns) which contain the intended consignee (ship to) and the activity to receive the bills and effect payment (bill to).
USED IN: AMREQUIS
REFS:

DEN:
NAME: SOURCR_FIL
LONG TITLE: Source File of the data element
PIC: X(50)
DESC: The files (relations) in which the data element
is used.
USED IN: DATALEM
REFS:

DEN:
NAME: STORAGELC
LONG TITLE: Storage Location (SAMS local data element)
PIC: X(30)
DESC: The location onboard a ship where particular
ammunition items are stored, ex. small arms locker,
ready service locker, Magazine (compt. number), etc.
USED IN: AMINVEN
REFS:

DEN: K048
NAME: SUPADDSERC
LONG TITLE: Service Designator Code of loadout activity
PIC: X
DESC: Supplemental Address Service Designator Code, loadout
point. A single alpha code that designates a service
or element of a service.
USED IN: AMREQUIS
REFS:

DEN: A002
NAME: SUPADDUIC
LONG TITLE: Unit Identification Code of loadout activity
PIC: X(5)
DESC: Supplemental Address UIC, loadout point UIC.
Identifies a ship or shore activity uniquely in
the manner specified by its service for accounting
and other purposes.
USED IN: AMREQUIS
REFS:

DEN:
NAME: TAGLABEL
LONG TITLE: Tag Label (SAMS local data element)
PIC: X(30)
DESC: A short narrative that is placed on the label that
must be attached to NAR affected ammunition to
explain the conditions under which it may be used
or if it may be used and to segregate it from other
unrestricted use ammunition.
USED IN: AMNARACT
REFS:

DEN: C010
NAME: TMDC
LONG TITLE: Type of Maintenance Due Code
PIC: A
DESC: A code indicating the type of maintenance to be
performed on the item of record. Applies to
torpedo MK 46 and ALM (Air launched Missiles).
USED IN: AMMODATA
REFS:

DEN:
NAME: TRNGALLOW
LONG TITLE: Training Allowance (SAMS local data element)

PIC: 9(5)
DESC: The unit-of-issue quantity of a particular ammunition item that a ship or unit is authorized to expend in a fiscal year for training. Promulgated in the 30000 series NAVSEA Shipfill Allowance List.

USED IN: AMALLOW
REFS:

DEN:
NAME: TURNINSTAT
LONG TITLE: Turn-in Document Status (SAMS local data element)
PIC: A

DESC: The status of a turn-in record line item, ex.-incomplete, ready to print or use as an input to an ATR, or ATR action complete.

USED IN: AMTURIN
REFS:

DEN: A002
NAME: UIC
LONG TITLE: Unit Identification Code
PIC: X(5)

DESC: Identifies a ship, shore activity, operational unit, agency, contractor, or other organized entity in the manner specified by the individual military service/agencies for accounting or other purposes.

USED IN: AMDADDR,AMSTDATA
REFS:

DEN: D192
NAME: UNITNAME
LONG TITLE: Activity Long Name (own ship)
PIC: X(45)

DESC: Name of own ship as listed in the Plain Language Address Directory (PLAD) if available, otherwise in the clear name.

USED IN: AMSTDATA
REFS:

DEN: C005
NAME: UNITOFISSU
LONG TITLE: Unit of Issue
PIC: AA

DESC: An abbreviation which represents a determinate amount or quantity and serves as a unit of measurement when issuing the item, ex. BX,EA,etc.

USED IN: AMMODATA
REFS:

DEN: B053
NAME: UNITPRICE
LONG TITLE: Unit Price
PIC: 9(10)

DESC: The price of the individual item of supply per unit of issue.

USED IN: AMMODATA
REFS:

DEN:
NAME: USED/FY
LONG TITLE: Training Allowance used in current fiscal year (LDE)
PIC: 9(3)

DESC: The quantity of a particular ammunition item that has a training allowance that has been expended in the current fiscal year for that purpose.

USED IN: AMALLOW

APPENDIX C

SAMS PROGRAM DIRECTORY

Program: AMSMAIN
 Calls: INFOMENU, INVMENU, TRANMENU, REQMENU, NARSMENU, REPTMENU,
 MANGMENU, TURNMENU
 Purpose: Main prg. that branches to all subsystem menus,
 intro. screen.
 Called By: PROTECT (dBase III+ security program)

Program: BCKUPATR
 Calls: none
 Purpose: Backups ATR file to another storage device for system
 protection.
 Called By: TRANMENU

Program: BCKUPNAR
 Calls: none
 Purpose: Backups NAR Serial and Action File for system
 protection.
 Called By: NARSMENU

Program: BCKUPREQ
 Calls: none
 Purpose: Backups Requisition File to another storage device
 for sys. protection.
 Called By: REQMENU

Program: BCKUPSYS
 Calls: none
 Purpose: Allows system manager to bacup all system files.
 Called By: MANGMENU

Program: BCKUPTUR
 Calls: none
 Purpose: Backups Turn-in File to another storage device for
 system protection.
 Called By: TURNMENU

Program: COMPLREQ
 Calls: none
 Purpose: Offers detailed review of requis. with all pertinent
 data.
 Called By: REQMENU

Program: CRENEWRO
 Calls: none
 Purpose: Creates new requis. with detailed user instructions
 Called By: REQMENU

Program: CRENWATR
 Calls: none
 Purpose: Allows user to create an ATR record, collects all data
 Called By: TRANMENU

Program: CRENWTID
 Calls: REWADD
 Purpose: Creates a turn-in/issue line-entry.
 Called BY: TURNMENU

Program: DATAELEM
Calls: none
Purpose: Allow the user to review the Data Element Dictionary
of the SAMS.
Called By: INFOMENU

Program: DOCCODES
Calls: none
Purpose: Presents system and CAIMS codes.
Called By: INFOMENU

Program: DOCDEFIN
Calls: none
Purpose: Presents system and CAIMS definitions.
Called By: INFOMENU

Program: DOCFILES
Calls: none
Purpose: Presents SAMS files and their purpose.
Called By: MANGDOC

Program: DOCPRGS
Calls: none
Purpose: Presents SAMS programs and their purpose.
Called By: MANGMENU

Program: DOCREFS
Calls: none
Purpose: Presents system and CAIMS reference documents.
Called: INFOMENU

Program: EDITATR
Calls: none
Purpose: Allows use to edit or delete non-committed ATR's.
Called By: TRAMMENU

Program: EDITREQ
Calls: none
Purpose: Allows editing and deleting of non-submitted
requisitions.
Called By: REQMENU

Program: EDITTURN
Calls: none
Purpose: Allows editing or deleting of non-submitted turn-in/
issue document.
Called By: TURNMENU

Program: INFOHELP
Calls: none
Purpose: Provide system operating help accessible throughout
program.
Called By: INFOMENU

Program: INFOMENU
Calls: INFOTEXT, INFOHELP, DOCCODES, DOCDEFIN, DOCREFS, DATAELEM
Purpose: Gives general system info. and help programs.
Called By: AMSMAIN

Program: INFOTEXT
Calls: none
Purpose: Give general system purpose, operation, and other
information.

Called By: INFOMENU

Program: INVALLOW
Calls: none
Purpose: Displays Allowance List information to SAMS user.
Called By: INVMENU

Program: INVAMMO
Calls: none
Purpose: Allows user to review generic ammunition data
Called By: INVMENU

Program: INVMENU
Calls: INVVIEW, INVAMMO, INVALLOW
Purpose: Allows user to review generic ammo data, inventory status, allowance.
Called By: AMSMAIN

Program: INVREPT
Calls: none
Purpose: Prints various inventory reports depending on user desires.
Called By: REPTMENU

Program: INVVIEW
Calls: none
Purpose: Allow user to review onboard inventory with various field items.
Called By: INVMENU

Program: MANGADHC
Calls: none
Purpose: Allows administrator to create ad hoc queries and views.
Called By: MANGMENU

Program: MANGARCH
Calls: none
Purpose: Allows administrator to archive old records.
Called By: MANGMENU

Program: MANGDOC
Calls: DOCFILES, PROGFILE, STRUCCRT
Purpose: Allows system manager to select various documentation files for view.
Called By: MANGMENU

Program: MANGEDIT
Calls: none
Purpose: Allows administrator to globally edit and delete system records.
Called By: MANGMENU

Program: MANGINIT
Calls: none
Purpose: Start-up and initialization instructions for administrator.
Called By: MANGMENU

Program: MANGMENU
Calls: MANGEDIT, MANGSEC, MANGARCH, MANGRECV, MANGADHC, MANGINIT, BCKUPSYS, DOCFILES, DOCPRGS
Purpose: Selects type of system management desired by system administrator.

Called By: AMSMAIN

Program: MANGRECV
Calls: none
Purpose: Allows administrator to recover system from failure.
Called By: MANGMENU

Program: MANGSEC
Calls: PROTECT (dBase III+ security program)
Purpose: Allows administrator to manage security and
access system.
Called By: MANGMENU

Program: MISCREQ
Calls: none
Purpose: Refers user to other doc. for abnormal requis.
operations
Called By: REQMENU

Program: NARSMENU
Calls: REVNARSF, REVNARAF, PROCNAR, BCKUPNAR
Purpose: Allows review of NAR file, stockcheck, action
file update, backup
Called By: AMSMAIN

Program: OSRQREPT
Calls: none
Purpose: Prints outstanding requisition internal reports.
Called By: REPTMENU

Program: PRINTATR
Calls: none
Purpose: Allows printing of the various types of ATR's.
Called By: TRANMENU

Program: PRINTREQ
Calls: REQ1348, REVWADD
Purpose: Allows printing of different requisition formats
Called By: REQMENU

Program: PRINTTUR
Calls: none
Purpose: Prints turn-in document.
Called By: TURIMENU

Program: PROCNAR
Calls: none
Purpose: Processes NAR message: stock check, update inventory,
retain data
Called By: NARSMENU

Program: PROGFILE
Calls: none
Purpose: Allows user to review and print system program file.
Called By: MANGDOC

Program: REPTMENU
Calls: INVREPT, OSRQREPT, TRALREPT
Purpose: Prints various internal system reports.
Called By: AMSMAIN

Program: REQ1348
Calls: none
Purpose: Prints screen display of DD Form 1348 with

data filled in.
 Called By: PRINTREQ

Program: REQMENU
 Calls: REVWREQ, COMPLREQ, CRENEWREQ, EDITREQ, MISCREQ, PRINTREQ,
 BCKUPREQ
 Purpose: Branches to all requisition processing sub-functions.
 Called By: AMSMAIN

Program: REVNARAF
 Calls: none
 Purpose: Allows user to review the NAR Action File.
 Called By: NARSMENU

Program: REVNARSF
 Calls: none
 Purpose: Allows user to review the NAR Serial File.
 Called By: NARSMENU

Program: REVWADD
 Calls: none
 Purpose: Allows user to review address file.
 Called By: PRINTREQ, PRINTATR, CRENWTID

Program: REVWREQ
 Calls: none
 Purpose: Offers summary(exec.) review of all requis. with
 most imp. data.
 Called By: REQMENU

Program: STRUCCRT
 Calls: none
 Purpose: Allows system manager to review the SAMS design
 structure charts.
 Called By: MANGDOC

Program: TRALREPT
 Calls: none
 Purpose: Prints Training Allowance internal reports.
 Called By: REPTMENU

Program: TRANMENU
 Calls: VIEWATR, CRENWATR, EDITATR, PRINTATR, BCKUPATR
 Purpose: Selects type of ATR management desired.
 Called By: AMSMAIN

Program: TURNMENU
 Calls: TURNREV, CRENWTID, EDITTURN, PRINTTUR, BCKUPTUR
 Purpose: Selects type of turn-in/issue management desired.
 Called By: AMSMAIN

Program: TURNREV
 Calls: none
 Purpose: Allows review of turn-in file.
 Called By: TURNMENU

Program: VIEWATR
 Calls: none
 Purpose: Allow user to review the ATR file.
 Called By: TRANMENU

    Requisitions require some coded information that is very
    difficult to remember. Each screen in this subprogram will
    ask you for information and offer a description of the
    information and the choices available to you. Some items
    are mandatory on a requisition, and the screen will tell
    you so, but it will not prevent you from leaving the item
    blank. It is important then that you check to make sure the
    requisition is complete before submitting it.

text
NOTE: The 4 digit julian date on a requisition that will be
transmitted by electronic media (radio) must be
equivalent to the date-time-group on the message. so
if your radio room or communications center can not
transmit the message on the day you think they will,
it might be best to leave the date blank below ( by
just pressing <RETURN>). Or you could put the date in
and change it later.
On a manual requisition, DD form 1348, this
requirement does not exist, so just put down the date
you expect to turn in the requisition.
Julian Date Format: (YDDD)
Y - last digit of current year (ex. 1987 - 7 )
DDD - julian day of year ( use 3M calendar )

text
    Naval message requisitions always go to SPCC Mechanicsburg,
    PA., N00104. Requisitions sent via DAAS format always go to
    DAAS (Defense Automated Addressing System), Dayton, OH.
    (Ref. SPCCINST 8010.12D)
    However, fleet instructions vary on who should receive
    requisitions if submitted by message(DAAS incl). Therefore you
    should indicate below who will receive the requisition or be
    the primary action addree on a message. This is necessary to
    assign the proper routing identification code.

    The supplemental address is the location where you plan to
    actually receive the material and load it out. You need to
    fill this in so that the supply system will know where to
    send the material and from which supply point to fill the
    order.

    The next screen will show you the most common supply
    activities and vessels in your area ( and beyond ).
    A complete list is in NAVSUP Pub. 485, App. 7.

?

text

The Priority Code (0-15) expresses the relationship between the requisitioner's assigned force/activity designator and the selected urgency of need designator, and determines the time frame within which the requisition will be processed. Basically it determines how big a wig you are and how fast they have to fill your order! If you don't know your unit's assigned force/activity designator check with the Supply Officer. The chart on the next screen will help you determine your priority code. Priority Codes are fully explained in NAVSUP Pub 485 sec. 3045-3049, it is worth reading once. Your unit can generally only use 3 of the Priority Codes since you have one assigned F/AD (Force/Activity Designator).

@ 1,15 say " Requisition Status "
?
text
  Requisition Status indicates the degree to which a
  requisition is complete, ready for submission, submitted but
  unfilled, etc.. It is a code established by this system
  (SAMS), and not the Navy supply system. The Navy supply
  system has many status codes of its own. This requisition
  status is for your use in managing your conventional
  ammunition requisitions, receipts, etc.. It will be used in
  SAMS in various ways.

  NOTE: The only item that may be left blank on a requisition
  you submit is the Advice Code. Therefore it is a good
  habit to simply assign appropriate values to all items
  that this program has requested.

  The next couple of screens will show you all the selections
  that you have made, the exact meaning of the status codes,
  and ask you to assign one. All the values shown have been
  written to the file, so in order to change any values we'll
  finish this part of the program and select the edit option
  from the "Requisition Management" menu, if desired.

I. General.

Cancellations, follow-ups and modifications to
requisitions are infrequent events that you may someday
have to do. Since these are not common, this program
only refers you to the publications that deal with them.
The SAMS program will still be useful to you in creating
these documents.

IMPORTANT ** Note that the fleet commanders and
operational commanders promulgate specific instructions
concerning ammunition requisitioning and reporting. As
weapons personnel you should keep current on these
because they deal with your ship's particular area of
operations.

Specifically:

text
    A DAAS formatted message is always UNCLASSIFIED because none
    of the MILSTRIP data elements contain classified
    information.
    NOTE: Other technical or operational information about a
           particular item may be classified however, such as
           for torpedoes, some missiles and rockets, etc..

    A narrative message is likewise UNCLASSIFIED unless you
    must add a REMARKS paragraph that contains classified
    information such as ship's schedule or other operational
    information.
    NOTE: CINCLANTFLT does not permit classified requisitions.
           A separate classified message is required.
